Docket #: S04-192

High Speed Videography

Stanford Researchers have patented an improved technique for capturing and processing dynamic and high speed scenes using a collection of precisely timed video cameras. This system uses multiple synchronized image sensors with precise time delays to capture high-speed video. If the cameras are closely packed together, the system can be used as a continuously streaming high-speed camera. If the cameras are spread further apart, the system can be used to capture multiviewpoint video of dynamic events (sports, performances, etc) at effectively higher frame rates without using expensive high-speed cameras and capture systems. Capturing with a higher effective frame rate simplifies space-time view interpolation creating new images of a scene that appear to have been taken from a place and time not in the captured set of images. An example would be slow-motion replay from a smoothly varying virtual camera position.

Applications

- High-speed videography
 - $\circ\,$ Sports: for analysis of athlete's performance or competition finishes
 - Medical testing
 - o Dance: for analysis of dancer's motion
 - Military test and evaluation
 - o Industry trouble shooting: manufacturing, vehicle impact testing, ect...
- Movie special effects
- Enhanced video playback for consumer television

Advantages

- Enables continuous streaming
- Longer capturing duration: minutes instead of seconds of video capture
- Eliminates the need for a trigger

- Cost-Effective: eliminates rolling shutter distortions allowing the use of inexpensive CMOS sensors
- Modular & Scalable can scale to higher speeds by simply adding more cameras to the array
- Processing of new visual outputs with minimal computational load
- Flexible
- Capture from widely spaced cameras with staggered trigger times enabling playback of real, live scenes from a variety of angles and varying speed for sports, dance, and other action filled scenes
