

Flexible Pressure Sensors

Researchers in Professor Zhenan Bao's group at Stanford University have created a thin-film pressure sensor device structure so sensitive it can detect the slightest touch. This ultrasensitive, highly flexible electronic sensor can detect something as light as a small fly of 20mg landing on it. The underlying architecture of the new sensor is a thin film of rubber molded into a grid of tiny pyramids and placed between two electrodes. The researchers have already produced a sheet of sensors that exhibited a great deal of flexibility, indicating the technology should perform well when wrapped around a surface mimicking the curvature of the human hand or the sharp angles of a robotic arm. This is a simple, cost effective technology for producing large arrays of tiny, high-resolution pixels; potential applications include electronic skin, prosthetics, biomedical applications, automobile industry, robotics, and touch sensors for displays and toys. A closely-related technology is Stanford Docket No. S10-252, "Three-dimensional Touch Technology for Intuitive Human-Computer Interaction," invented by Zhenan Bao and Benjamin Tee.

Researchers can measure the pressure from a butterfly registered by the sensors.

NPR "All Tech Considered" Feature

["Just Like Human Skin, This Plastic Sheet Can Sense And Heal"](#), April 11, 2016

Applications

- Pressure sensors
- Liquid or gas flow sensors
- Weight measuring device
- Tactile sensors
- Artificial skin for use on prosthetic limbs or robots
- Biomedical ("feel" the cancer cells vs. healthy cells, for example)

- Pressure sensors for biomedical devices
- Can be used on a transistor/semiconductor to get current read-out
- Touch sensors for displays and toys

Advantages

- Highly sensitive
- Quick rebound time
- Can be used on flexible substrates
- Can be made stretchable
- Easily integrated into existing technologies that make touchscreens
