

A New, Integrated Method of Human or Animal Body Modeling with Applications for Animation and Tracking

Stanford researchers have patented a data-driven method for building a human shape model that spans variation in both subject shape and pose. The method is based on a representation that incorporates both articulated and non-rigid deformations.

Capabilities include partial-view completion and lifelike animation of marker motion-capture sequences. Specifically, this method is capable of constructing a high-quality animated surface model of a moving person, with realistic muscle deformation, using just a single static scan and a marker motion capture sequence of the person.

Figure

Figure description - Animation of a motion capture sequence taken for a subject, of whom we have a single body scan. The muscle deformations are synthesized automatically from the space of pose and body shape deformations.

Applications

- Animation and computer graphics
- Digital movies
- Interactive Gaming and video games industry
- Biomechanical and clinical applications
- Biofeedback and rehabilitation
- Design and engineering
- Ergonomics
- Digital simulation of human and animal interaction
- Education
- Art. Visual arts and any art using biological signals as an input or output.
- Robotics. Development of biomimetic robots
- Surveillance

Advantages

- **Captures body deformations** due to change in pose and body shape variation between different individuals
- **Maintains proper deformation scaling**
- **Efficient** shape-completion of different subjects in different poses
- **Enables marker-less motion capture** of different people and animals from any kind of 3D readings, including stereo cameras, or multiple camera feeds combined, using shape-from-silhouette techniques, or the input from any 3D range sensors
- **Accurate** - The shape-completion capability provides accurate subject-specific automatic segmentation
- **Low cost** - The integrated method saves production time and cost
