

MEMS sensors from epitaxially grown piezoresistors

Stanford engineers have created a patented method for fabricating highly sensitive piezoresistors on vertical walls of microstructures by epitaxial growth of doped silicon. In-plane inertial sensors produced with this technique are up to 7 times more sensitive with a lower noise level than their ion-implanted counterparts. These benefits are achieved by growing mono-crystalline piezoresistors on a mono-crystalline substrate (epitaxial crystal growth), which creates an efficient, high-quality sensing structure. End user applications for this technology include accelerometers, gyroscopes and shear stress sensors.

Scanning electron microscopy (SEM) image of sidewall epitaxial piezoresistors on an unreleased cantilever using a selective deposition process.

Stage of Research

The inventors built and tested the piezoresistors and demonstrated sensitivity and resolution comparable to single-crystal ion implanted piezoresistors and better than most polysilicon or diffusion-based piezoresistors.

Applications

- **Force sensors** - higher quality, smaller inertial and force sensors with end user applications such as:
 - Accelerometers
 - Gyroscopes
 - Shear stress sensors
 - Other in-plane force and stress sensors

Advantages

- **Sensitive** - better sensitivity and lower noise than implanted piezoresistor based sensors and other current options
- **Simple and scalable:**
 - piezoresistors offer greater simplicity and miniaturization than optical and capacitive type sensors
 - potential to miniaturize sensors to sub-micron or nanoscale sizes
- **Better force resolution**
- **Robust** - low susceptibility to heat variation
