Docket #: S12-437

Self-Healing Electrode for Lithium Ion Battery

Stanford researchers have demonstrated a self healing electrode that can dramatically enhance the cycle lifetime of lithium ion batteries by applying Si microparticles with a thin layer of self-healing conductive composite. Cracks and damages in the electrode over the large volume changes of Si materials during lithiation and dilithiation were found to be able to self-heal automatically and thus greatly enhance the cycling stability. Batteries with these self-healing anodes have superior capacity and can cycle more than 100 times in half cells while retaining more than 80% of their initial capacity. The cycling lifetime is more than **ten times** longer than state-of-the-art anodes of Si microparticles.

Stage of Development – Prototype
Researchers have attained a cycle life ten times longer than state-of-art anodes made from SiMPs and still retained more than 80% of their initial capacity (up to ~3,000 mA h g?1). The Yi Cui Group continues to refine and improve performance and longevity by testing other self-healing polymers and electrode materials.

Applications

- For all types of lithium ion batteries to improve the cycling lifetime including those used in cell phones, electric vehicles, consumer electronics, and electrochemical devices.

Advantages

- Self-healing – this polymer coating can repair cracks within a few hours.
- Cycling lifetime can be increased by more than 10 times
- Cycle more than 100 times in half cells while retaining more than 80% of their initial capacity
- Low cost
