Docket #: S14-387

Position/force control of a flexible robot under model-less control

Stanford researchers in the Camarillo Lab have patented a model-less, robotic position-control technique that regulates force. The controller simultaneously controls position and applied forces of the manipulator as it moves through a workspace, without requiring a model. In addition, the robot traces paths along the environment while a specified amount of force is maintained and not exceeded. This model-less control technique is ideal for medical robotics where small, flexible devices navigate constrained and highly sensitive environments.

Stage of development - Prototype

Applications

- **Flexible robotics**
- **Medical robotics**
    - Catheters
    - Endoscopes

Advantages

- Accurate – especially in constrained spaces
- Constant – maintains safe levels of constant contact
- Adaptive - navigates irregular and unpredictable constrained spaces
