

Docket #: S17-318

Patterned and instrumented directional adhesives for enhanced gripping with industrial manipulators

Researchers in Dr. Cutkosky's laboratory have developed a gripper device that allows industrial robots to handle very soft or delicate objects. Effective handling of delicate objects remains a challenging problem in manufacturing. To address these challenges, Stanford researchers use gecko-inspired directional adhesives attached to an industrial robot gripper with a tactile sensor. With these enhancements, the robot uses a very low grasp force to sustain loads in any direction, avoids load dropping and slipping, and the load remains residue-free when the grip is released. This technology is applicable to robotic tasks with delicate or soft objects.

Fig. 1: An industrial robot using gecko-inspired adhesives on the gripper pads can grip and manipulate a rotten tomato and a raw egg gently and reliably.

Applications

- Industrial robotics
- Medical and surgical robotics

Advantages

- Improved handling for robotic manufacturing tasks with delicate or soft objects.
- A much lower grip force needed than would be possible using conventional materials such as rubber pads.
- Reliably predicts the maximum force and moment that can be applied without slipping.
