# **Full-duplex wireless adaptive tuning techniques**

Stanford researchers have invented techniques to adaptively tune the operation of a wireless full-duplex node. To enable full-duplex operation, the receiver circuit needs to be able to cancel the transmitter's signal in order to receive data from other nodes.

The two components of the self-interference cancellation system are 1) Cancellation in the Radio Frequency and 2) Cancellation in Digital Samples.

This invention implements adaptive techniques for both components of the full-duplex design to make the design practically implementable.

## **Stage of Research:**

This method has been evaluated using a 5 prototype testbed for a 10MHz wide OFDM signal. In this evaluation, full-duplex reduces packet losses due to hidden terminals by up to 88%. It also mitigates unfair channel allocation in AP-based networks, increasing fairness from 0.85 to 0.98 while improving downlink throughput by 110% and uplink throughput by 15%. These experimental results show that a redesign of the wireless network stack to exploit full-duplex capability can result in significant improvements in network performance.

## **Applications**

- Wireless network deployments in enterprises and institutes
- High performance home wireless solutions
- Multi-hop wireless deployments
- Cellular backhaul

## **Advantages**

- **Full-duplex wireless advantages:**
  - Simultaneous, two-way transmission on the same frequency
  - Faster, more efficient, and robust communication networks
  - Up to double the throughput of current wireless systems in single hop wireless systems. With intelligent medium access designs, the gains are even more for both single and multi-hop wireless systems
  - Helps solve the hidden-terminal problem
  - Improves fairness in WLAN networks
  - Reduces the end-to-end latency in multihop networks.
- This design can adapt to design parameters 'on-the-fly'
- This design can work with MIMO systems
